

🎨 Theme Switcher

Step 1: Layout

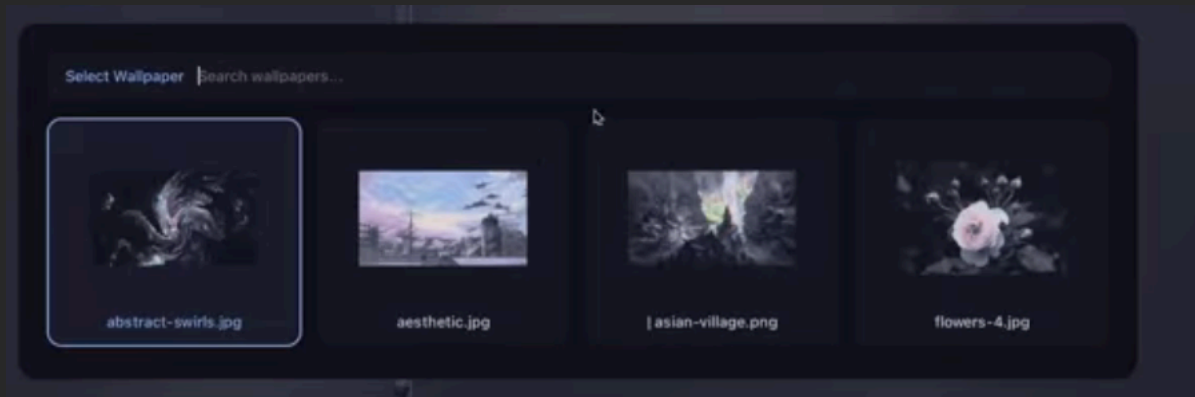

** Follow layout of HyprGruv settings; this is mainly for how the buttons are laid out and options underneath

Layout for the color palette should follow look-and-feel styling icons to the settings Rofi

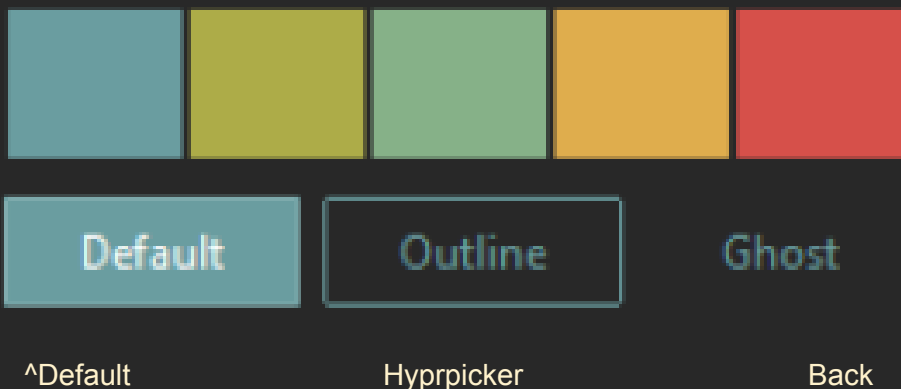

Use this 'styling' for font transition, blur, format ** except that this will be in one line like the color palettes from below

Needs to be more of a scrolling horizontally type rofi; example layout is in
~/Documents/Hypercourse/meridian/.config/rofi

Do not need to put the color names because it is not consistent across palettes (ie some have 2 greens and not a red, blue, green, cyan)

Along these lines, for just the way the buttons look with 'Default' and 'HyprPicker', and ...

Top Drop Down:

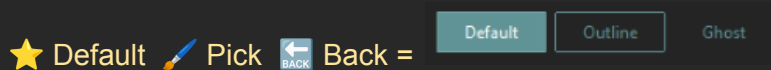

**No Dropdown Menu Needed (theme already chosen) > Just Needs Header with 'Select Primary Color'
Using System font

Middle Panel:

One panel with the colors from palettes (scroll left to right through palette; highlight the selected with the new theme's primary source color/ the rest of the theme is standard, choices, if the source color chosen via the rofi palette is used in the theme for other color values then swap with the standard/default' source color)

Bottom panel persistent with:

Step 2: Fix Awkward Active Window Border, bring image

In the current version, the picture previews have an unfilled border between the 'active selection' border and the image, which makes an awkward tap on the top and bottom that is not noticed until the image is selected; the image should expand out past the edge and be cropped by the border

Instead of showing active by putting a border around the front to cover and create awkward gaps, show a reverse shadow, i.e., make it activate as brighter through a shadow that would sit behind the provided previews and color palettes in the next selection pane

- Add a slight size change and shadow (in light color) to highlight which color or option is selected on hover or through using arrow keys > use the same method as wlogout
- I would say do it in a color from the palette, but it's pretty unpredictable, so just an 'off-white' consistent across all themes would probably be less gawdy

Step 3: Tidying Up

- ☐ Check the source and primary colors
- ☐ Check terminal colors for readability.
- ☐ Go down the list with each main theme
- ☐ For some themes, they may only have 1 or 2 source colors (exe noir, which will have the same source color each time /slate blueish grey)
- ☐ The images are getting scrnched slightly where there are 3 rows total but have to scroll down just like an inch to see the theme name on bottom row / either adjust adding or perimeter size to accomodate

Step 4: App Integrations

- ☐ Make hyprrbars persistent/not change depending on selected source color for consistency > check per theme and ensure that they go in rainbow order (visually appealing)
 - ☐ For themes without a standard palette, develop starships that are readable with color schemes / for example, a noir starship is barely visible in the first cells because the text is washed out; it should have a contrasting color, and usually the same color for all of the lighter-shaded cells
- For non-standard themes, ensure that the appropriate cursor, icon, and Yazı are applied.

Notes on Theming:

- ☐ Delete unused wallpaper that doesn't really match the theme
- ☐ Strip down noir to just a handful of wallpapers
- ☐ <https://www.color-hex.com>

Chrome: Base16 Everything

```
> what is currently styling my google chrome so that it looks like chocolately gruvbox awesomeness and how do i save this configuration to be used on future devices or if i have to reset this device? 12:18 PM
```

Base16 Everything (this is the Gruvbox)

Saved settings:

- Light scheme: `gruvbox-light-hard`
- Dark scheme: `google-dark` (the free-tier dark default)
- Auto-apply: you've toggled this; last stored value is `false`
- Site exception: `desk.zoho.com` was excluded at one point

On real sites (google.com, myaccount.google.com, Zoho, etc.) the scheme it actually cached is `gruvbox-light-hard`. That warm cream / brown / mustard palette is the "chocolately Gruvbox."

Free themes in this extension are only those two. A darker chocolate `gruvbox-dark` variant is behind their premium/license unlock. I did not find a license key stored on disk, and the native-messaging host from [base16_everything_home](https://github.com/mat-his/base16-everything_home) (https://github.com/mat-his/base16-everything_home) is **not** installed.

To turn the look back on here: `chrome://extensions` → enable Base16 Everything → grant it access to sites → click the icon and turn auto-apply on.

Tabliss (new tab, when you want it)

Your Tabliss config is the matching furniture, not the page remapper:

- Widget text colors `#dac49f` and `#b5a487` (Gruvbox beige)
- Font: `ShureTech Mono`
- Unsplash backgrounds, literature clock, links, notes, Raleigh weather

Vimium C (still live)

Custom CSS is installed and active. It defines the Gruvbox palette (`#282828`, `#ebdbb2`, `#fabd2f`, ...) and forces `ShureTechMono Nerd Font` on hints / HUD / Vornibar. Your custom key maps and search engines live here too.

1. Portable recipe (best)

Keep this somewhere durable (notes, git, password manager):

1. Install Base16 Everything
 - Light: `gruvbox-light-hard`
 - Dark: `google-dark` (or a premium `gruvbox-dark-*` if you buy/unlock it)
 - Turn auto-apply on
 - Re-add any site exclusions (Zoho Desk if you still want that)
 - If you have a paid license, copy it out of the extension's Settings page
2. Install Tabliss
 - Enable it, then in Tabliss settings use **Export** and save the JSON
3. Install Vimium C
 - Options → **Export** (this grabs CSS, key maps, and search engines)
4. Install `ShureTechMono Nerd Font` on the new machine (Tabliss + Vimium both depend on it)
5. Optional: Stylus, only if you still want Dark Google Docs

Tabliss and Vimium C already write to Chrome's Sync Extension Settings, so those two often follow your Google account. Base16's settings folder has no sync copy on this profile.

2. Export from the UIs (do this before a reset)

- **Tabliss**: enable it → open a new tab → gear → **Export**
- **Vimium C**: `chrome://extensions` → Vimium C → Details → Extension options → **Export**
- **Stylus** (if you re-enable it): **Manage** → **Export**
- **Base16 Everything**: no real export UI; write down the two scheme names and any license key

3. File-level backup (survives a wipe of this Mac)

Quit Chrome first, then copy:

```
~/Library/Application Support/Google/Chrome/Default/Local Extension Settings/jmofeahfkeohbpbbedgbnkdlfaomjbnkf
~/Library/Application Support/Google/Chrome/Default/IndexedDB/chrome-extension_jmofeahfkeohbpbbedgbnkdlfaomjbnkf_0.indexeddb.leveldb
~/Library/Application Support/Google/Chrome/Default/Sync Extension Settings/hipekcciheckooncpjeljhnekcoolahp
~/Library/Application Support/Google/Chrome/Default/Sync Extension Settings/hfjbmagddngcpeloejdejnfgbamkjaeg
~/Library/Application Support/Google/Chrome/Default/Local Extension Settings/hfjbmagddngcpeloejdejnfgbamkjaeg
```

On a new machine: install the three extensions, quit Chrome, drop those folders into the new profile's matching paths, reopen Chrome.

The pack lives in your HyprGruv tree so the same files can seed this Mac and your Arch boxes.

On this Mac I already:

- Linked `~/config/hyprgruv` + `~/Documents/HyprGruv-main/home/.config/hyprgruv`
- Linked `~/local/bin/chrome-gruvbox`
- Wrote `~/config/base16-everything/config.yaml` as Gruvbox Dark Hard
- Registered the Base16 native host for Chrome and Brave (macOS + Linux paths)

What you run

```
chrome-gruvbox status      # what's installed vs missing
chrome-gruvbox restore     # new device / after a Chrome reset
chrome-gruvbox backup      # refresh the pack from a live profile
chrome-gruvbox apply-palette --dark    # static chocolate (default)
chrome-gruvbox apply-palette --light   # the cream scheme this Mac was applying to sites
chrome-gruvbox apply-palette --matugen # Arch only, follows wallpaper
```

`restore` installs the native host, writes the palette, and opens the store pages. Chrome still needs a few clicks after that:

1. Install Base16 Everything and Vimium C (Tabliss optional)
2. Base16 popup + light `gruvbox-light-hard`, dark `google-dark`, auto-apply on
3. Exclude `dark.zoho.com` if you still want that
4. If you have a Base16 license: Settings + grant native messaging, then reload tabs. That is what makes Chrome/Brave follow `~/config/base16-everything/config.yaml` (and matugen on Arch)
4. Vimium C options + Import +
`~/config/hyprgruv/chrome-gruvbox/vimium/vimium-c.json`
5. Install ShureTechMono Nerd Font on each machine (it is not on this Mac right now)

Where it lives in the Arch dots

```
home/.config/hyprgruv/chrome-gruvbox/ # portable snapshot
home/.config/hyprgruv/scripts/chrome-gruvbox.sh
```

`install-base16-everything-host.sh` now writes manifests on macOS and Linux. `setup-base16-everything-browsers.sh` calls the new pack after the existing matugen sync.

On an Arch box, after this tree is stowed (or copied to `~/hyprgruv`):

```
~/config/hyprgruv/scripts/chrome-gruvbox.sh restore
# or, if you already ran the HyprGruv browser setup:
~/config/hyprgruv/scripts/setup-base16-everything-browsers.sh
```

Where it lives in the Arch dots

```
home/.config/hyprgruv/chrome-gruvbox/ # portable snapshot
home/.config/hyprgruv/scripts/chrome-gruvbox.sh
```

`install-base16-everything-host.sh` now writes manifests on macOS and Linux. `setup-base16-everything-browsers.sh` calls the new pack after the existing matugen sync.

On an Arch box, after this tree is stowed (or copied to `~/hyprgruv`):

```
~/config/hyprgruv/scripts/chrome-gruvbox.sh restore
# or, if you already ran the HyprGruv browser setup:
~/config/hyprgruv/scripts/setup-base16-everything-browsers.sh
```

Status on this machine

Profile	Base16	Vimium C	Tabliss
Chrome Default	installed	installed	installed, disabled
Chrome Profile 1 (Work)	missing	missing	missing
Brave Profile 3	missing	installed	missing

`status` also noted Chrome is running, so quit it before a `backup` if you want a clean LevelDB read.

One intentional fix in the snapshot: Cliq's Vimium keyword is `cl` now. Live config had both Gusto and Cliq on `ci`, so Cliq could never win.

`vimium/search-engines.txt` and `vimium-c.json` include work URLs (Zoho, iAccess, etc.). If `hyprgruv` is public, keep those two files out of the push.

Worked for Rm77z

☑ Getting an error from the image; need to resolve

☑ “Only choice after theme – Ese = theme default – theme standard apply

The following warnings were detected when starting rofi:

Validating the theme failed: the variable ‘selected-normal-background’ in ‘element selected {background-color: var(selected-normal-background);}’ failed to resolve.

Do not need to have names of the colors,s as they may not be the same for palettes; need to just have colors from the screenshots saved in a file
